

# Use of Multi-Master PTP to Mitigate Faulty Masters Reporting as Healthy

Doug Arnold  
Meinberg-USA  
WSTS 2015  
San Jose

1. A weakness with PTP
2. Proposed solution for PTP: multi-master PTP
3. Voting algorithms
4. Simulations results
5. Conclusions

# Single Point of Failure!

## General approach

Compare multiple sources of time and remove any which are “different” from the rest

Bad time sources can be identified if they make up less than half of the number available sources

## GPS Timing receivers

TRAIM

In timing mode (using fixed position)

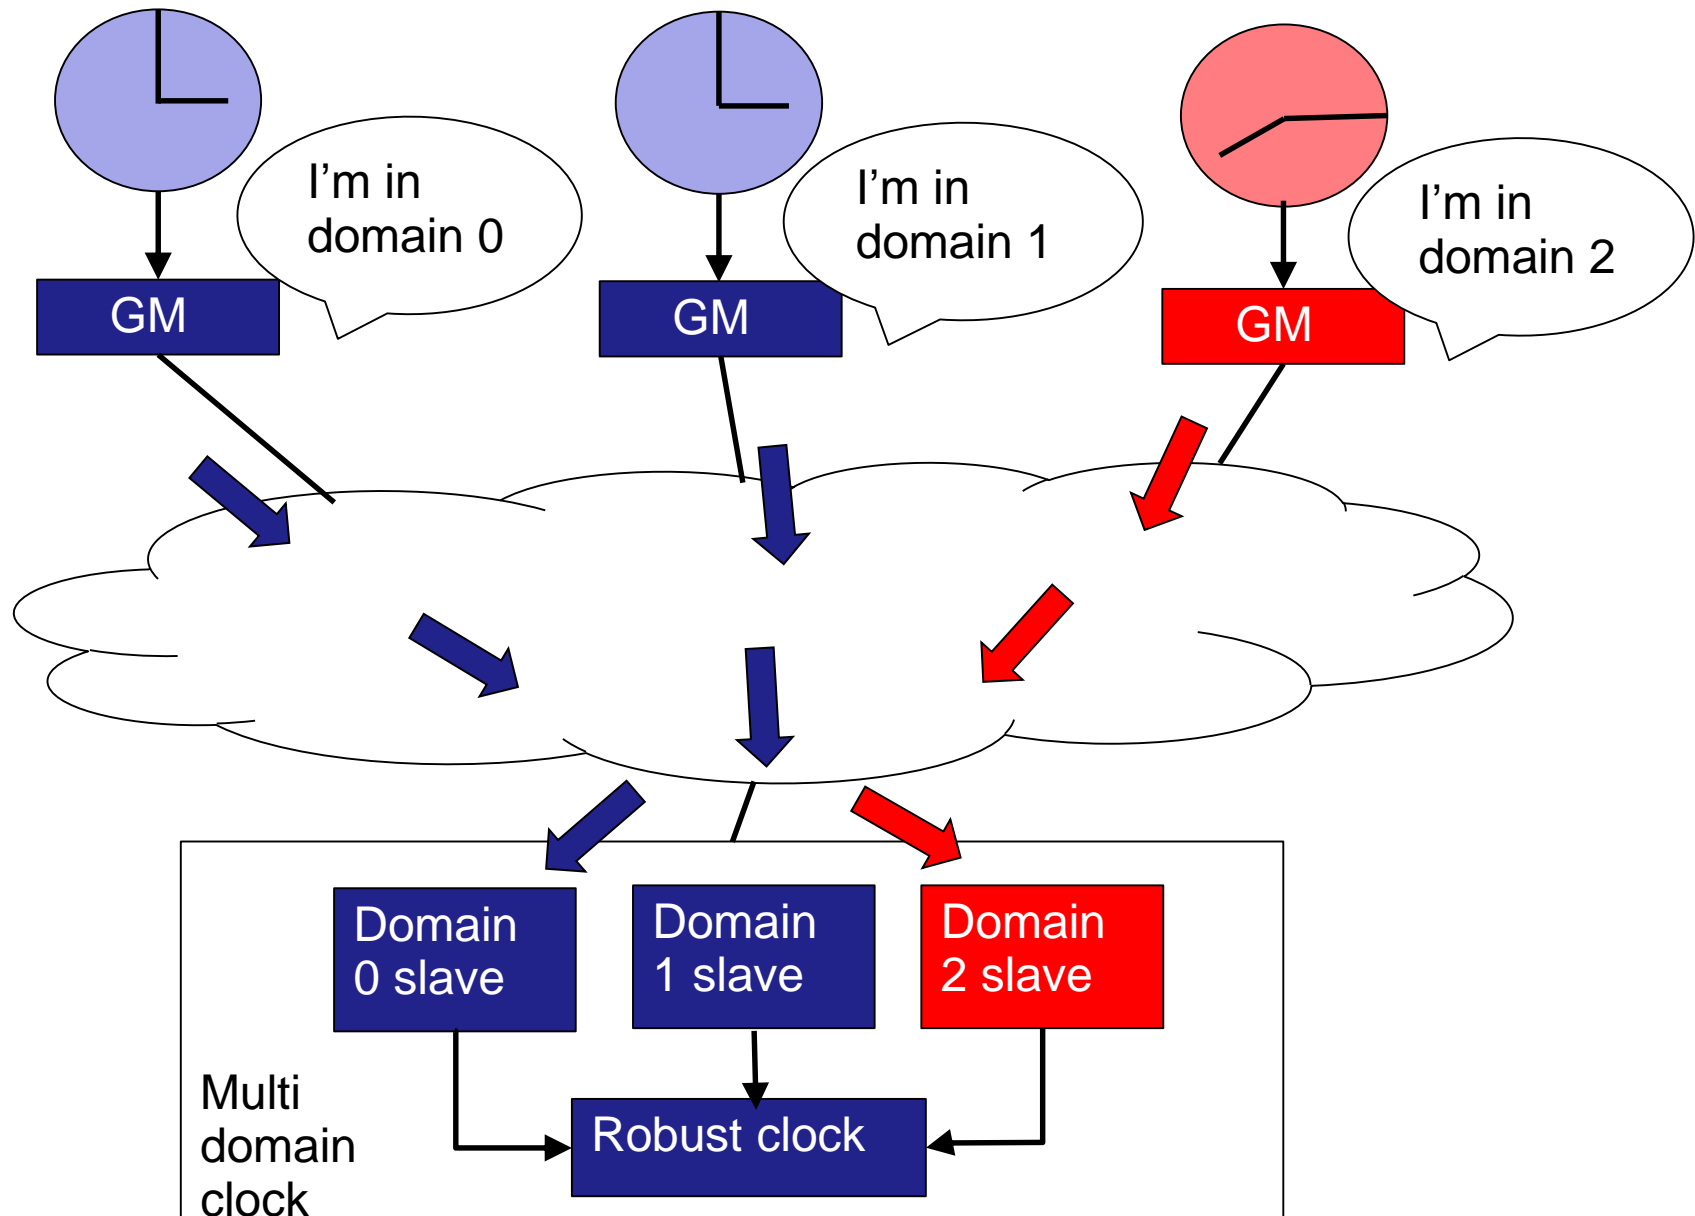

## NTP

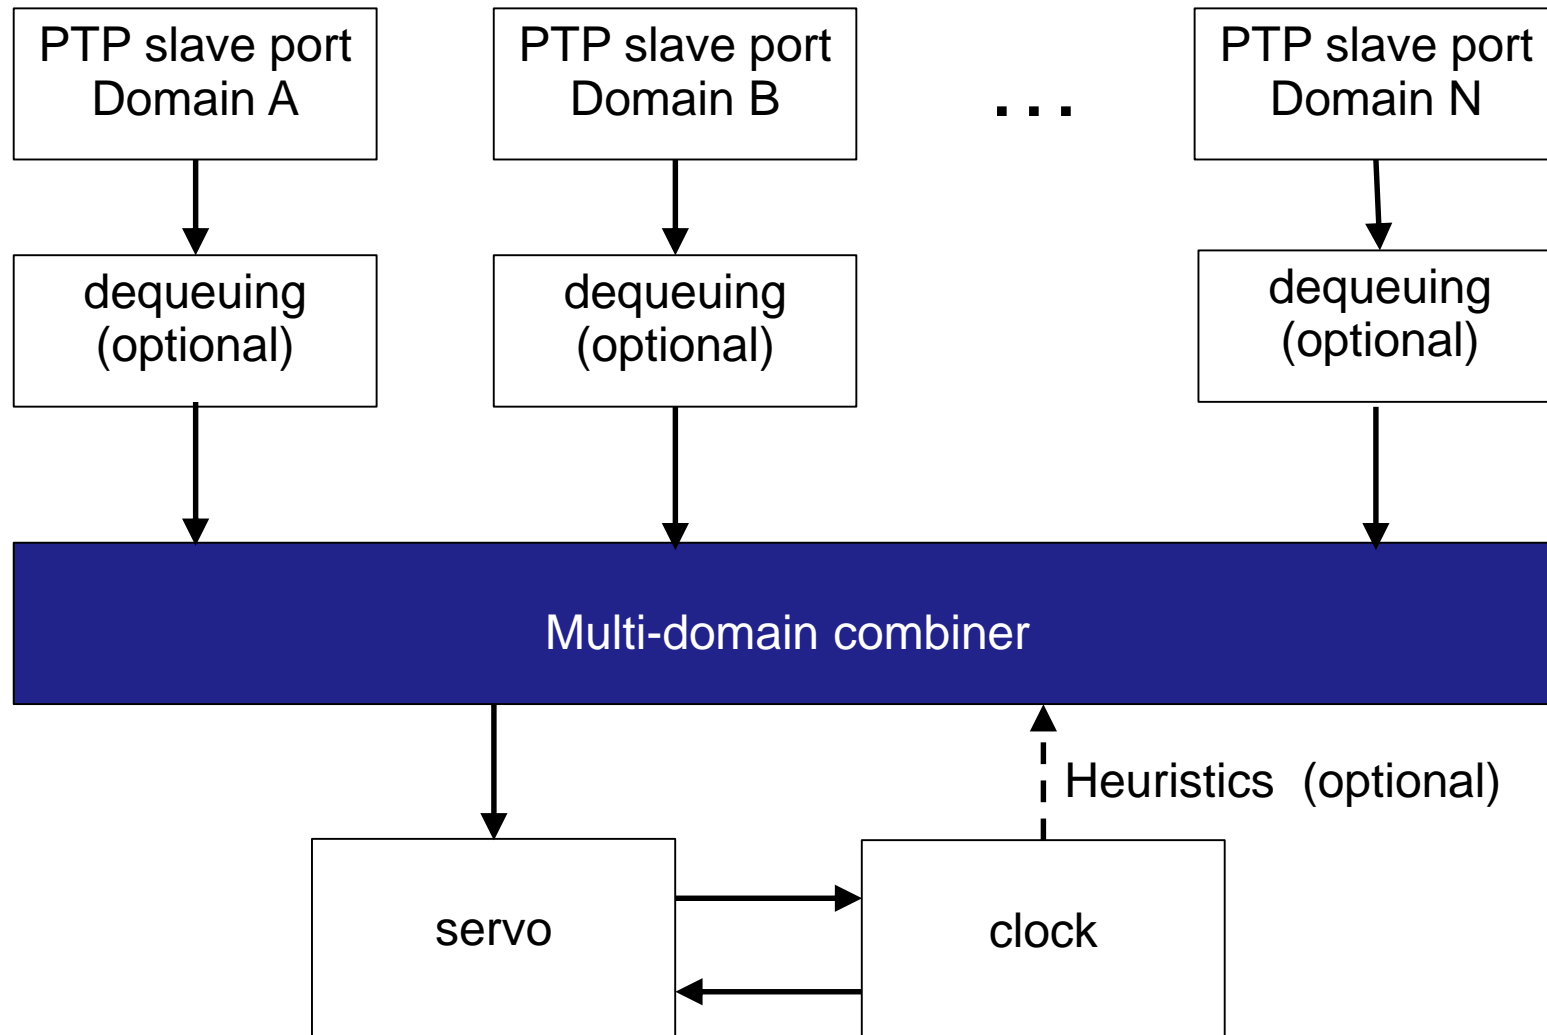

False tickers identification algorithm

## From robust statistics

Use median value from population

Insensitive to outliers, even with very large errors

## Timing Receiver Autonomous Integrity Monitoring

Described at ION-GPS 1996-1998 by Motorola

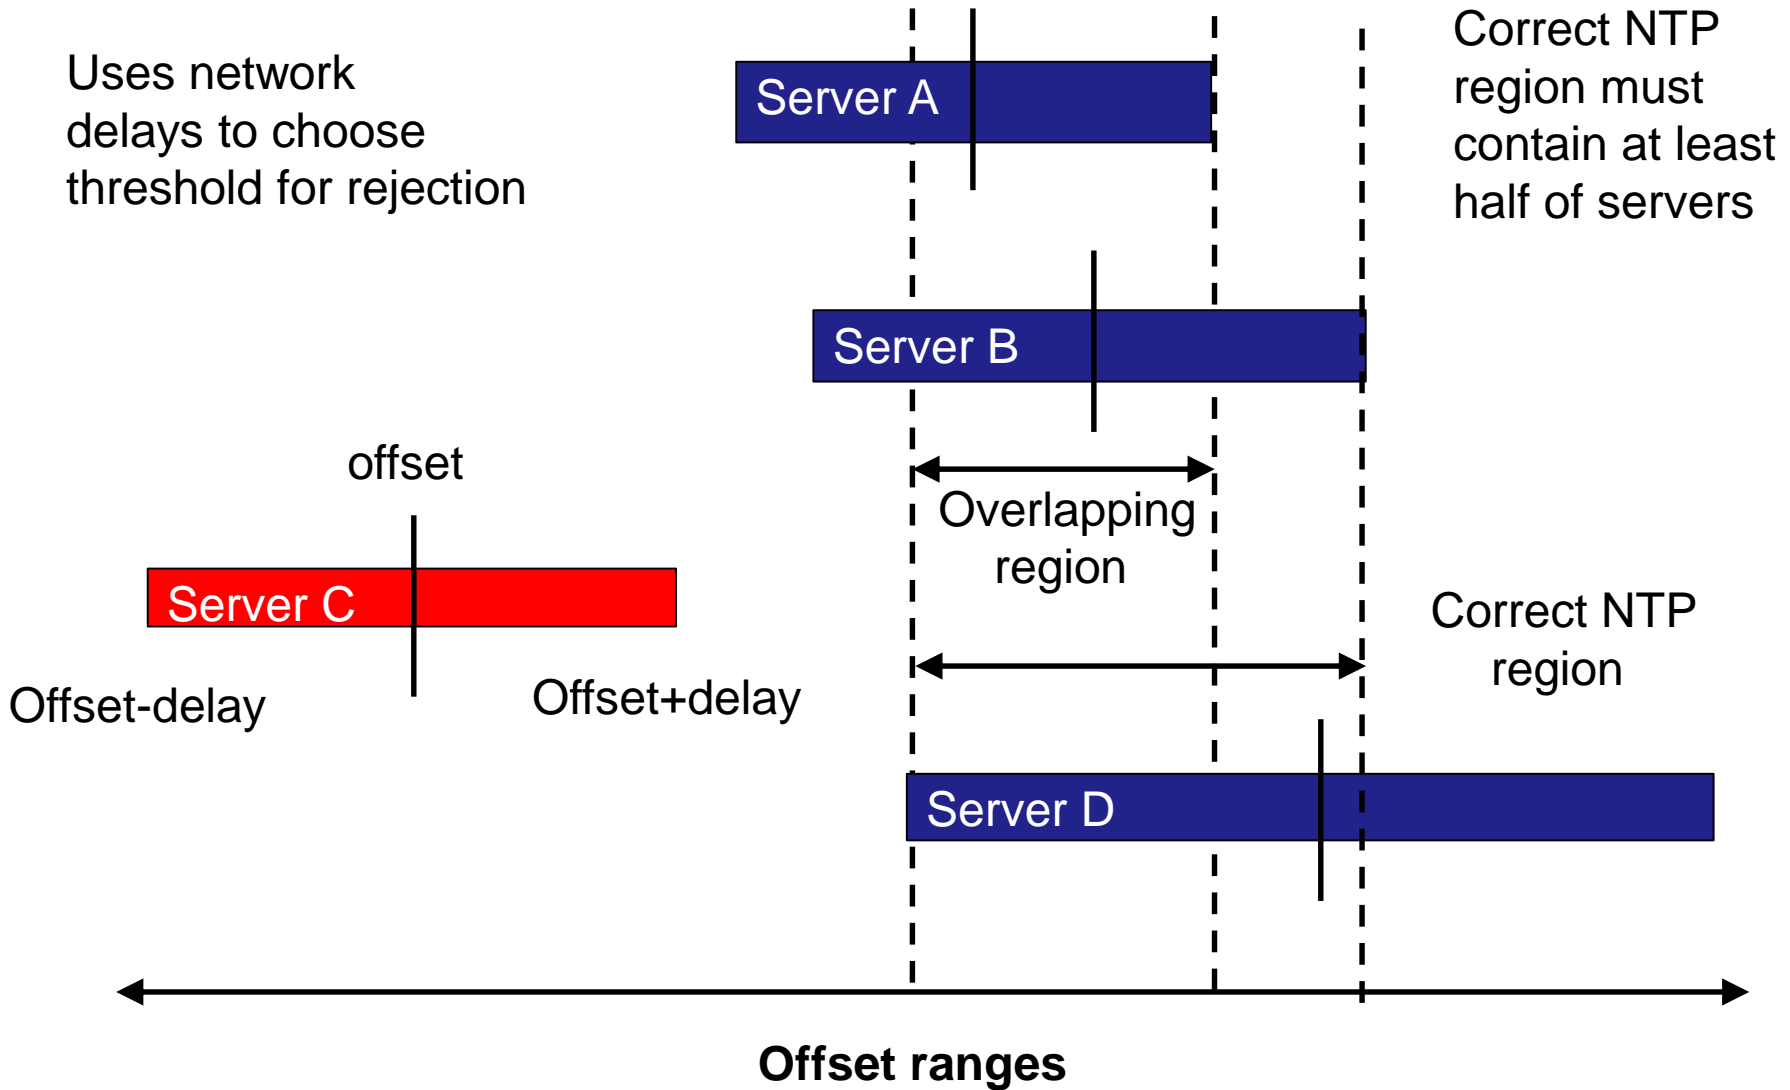

Looks at clock offsets only, not propagation delay

Threshold offset for bad satellite identification (user configured)

### Recursive Algorithm

0. GPS receiver in timing mode with a known position
1. Obtain local clock offset with respect to each satellite
2. Compute the mean\_offset
3. If  $|\text{Offset}(i) - \text{mean\_offset}| > \text{max\_offset\_deviation}$ 
  - Remove satellite(i) from calculation
  - Goto step 1
4. Stop when all offsets are within the max\_offset\_deviation of the mean
5. Or when the number of satellites  $< 3$
6. Use mean\_offset with bad satellites removed

PTP: Satellite = domain

## When to exclude time sources

- Median: always exclude all but median
- TRAIM : up to half +1 if they are over threshold from average
- NTP: only when majority of clocks agree with each other

## Threshold for exclusion

- TRAIM: manually set and fixed
  - OK for GPS where noise properties are relatively constant
- NTP: determined by network delay
  - Good worst case error for NTP dominated by raw queuing noise
  - Automatically changes with different network delays

## Adapting NTP algorithm to PTP

- Need different criteria for determining offset ranges
  - Range of offsets in a window?
  - Standard deviation from recent data?

## Focus on source selection

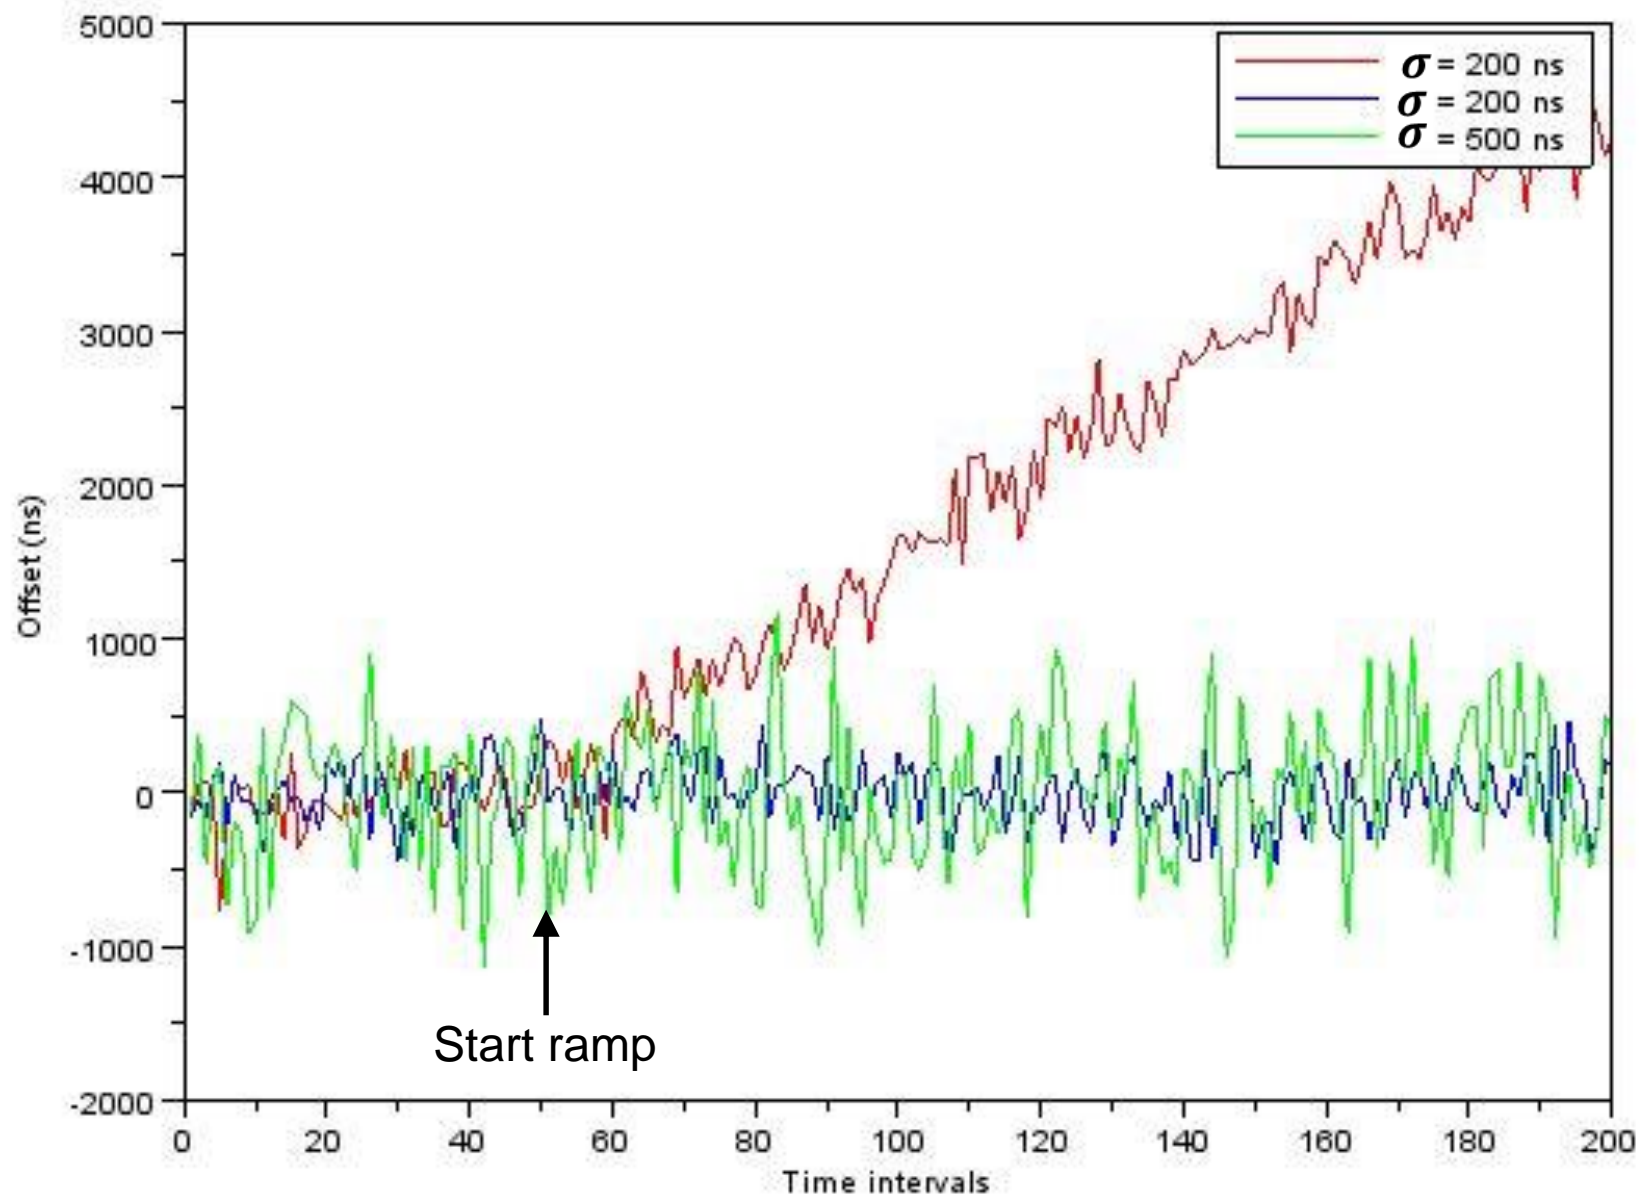

- Ignore dequeuing filters
- Ignore servo-loop filters

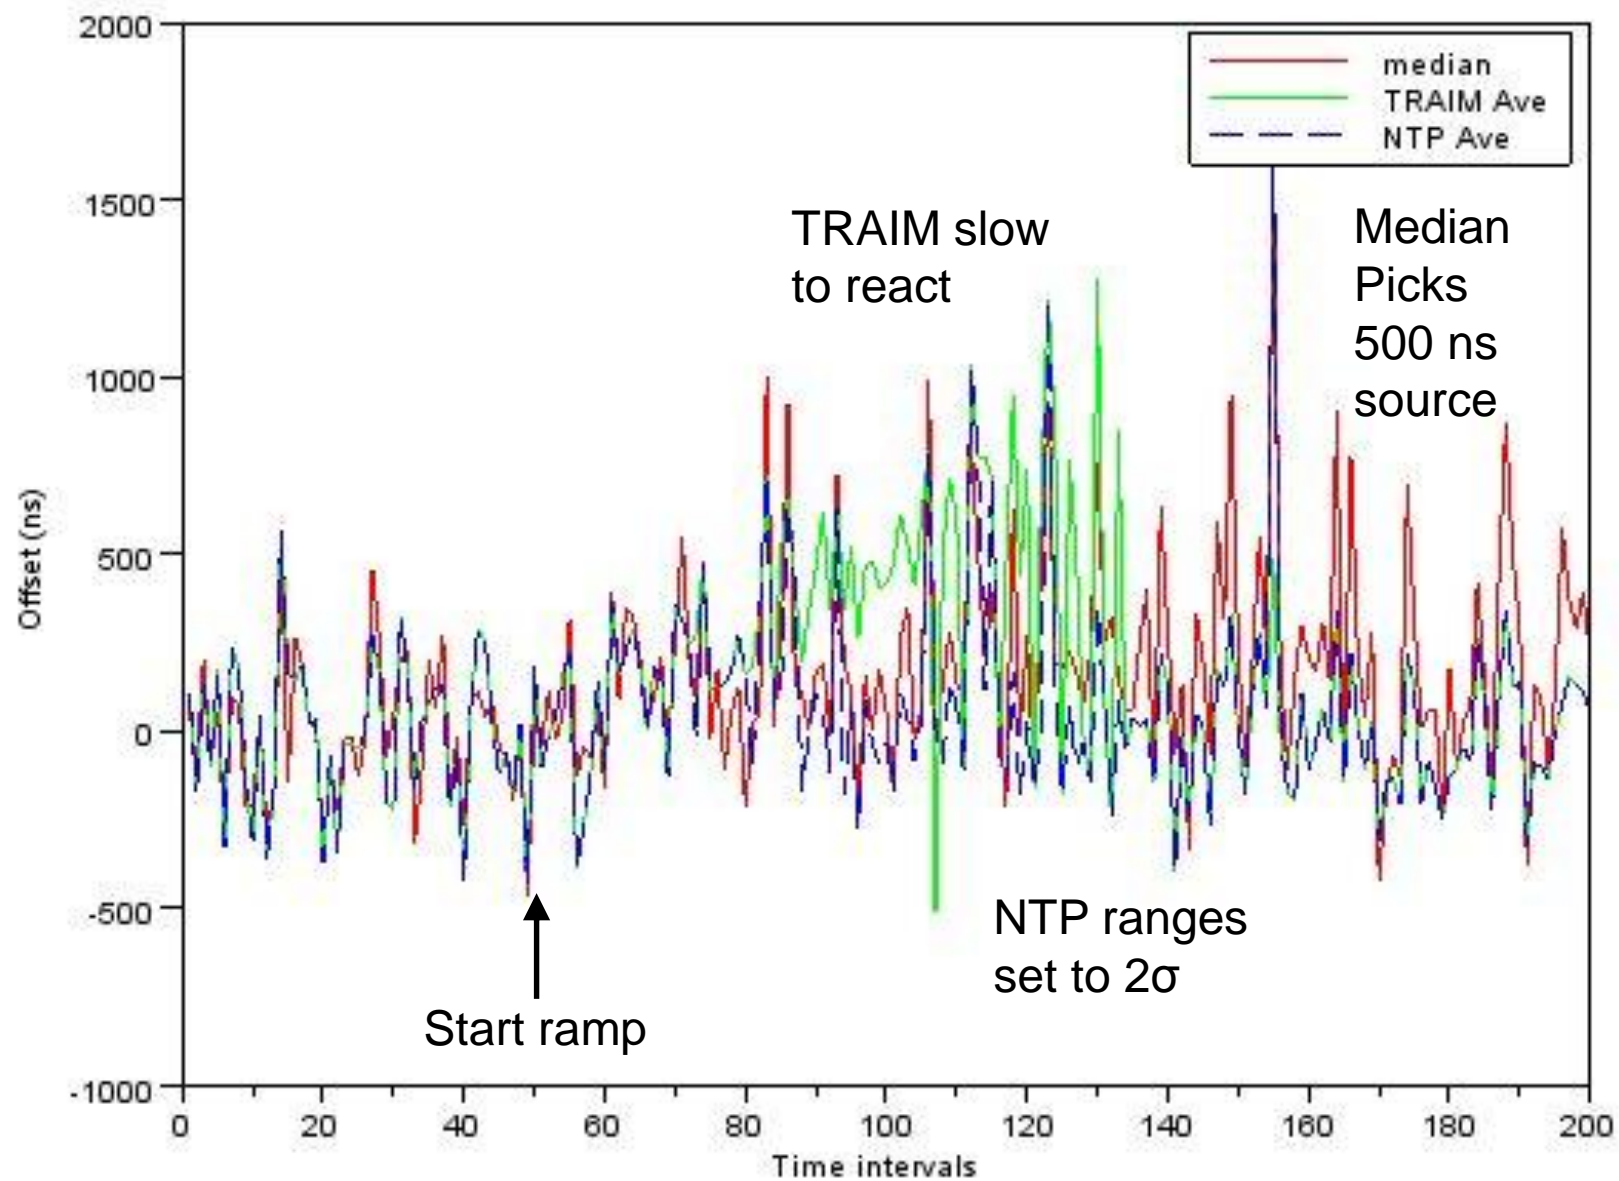

## Source selection type

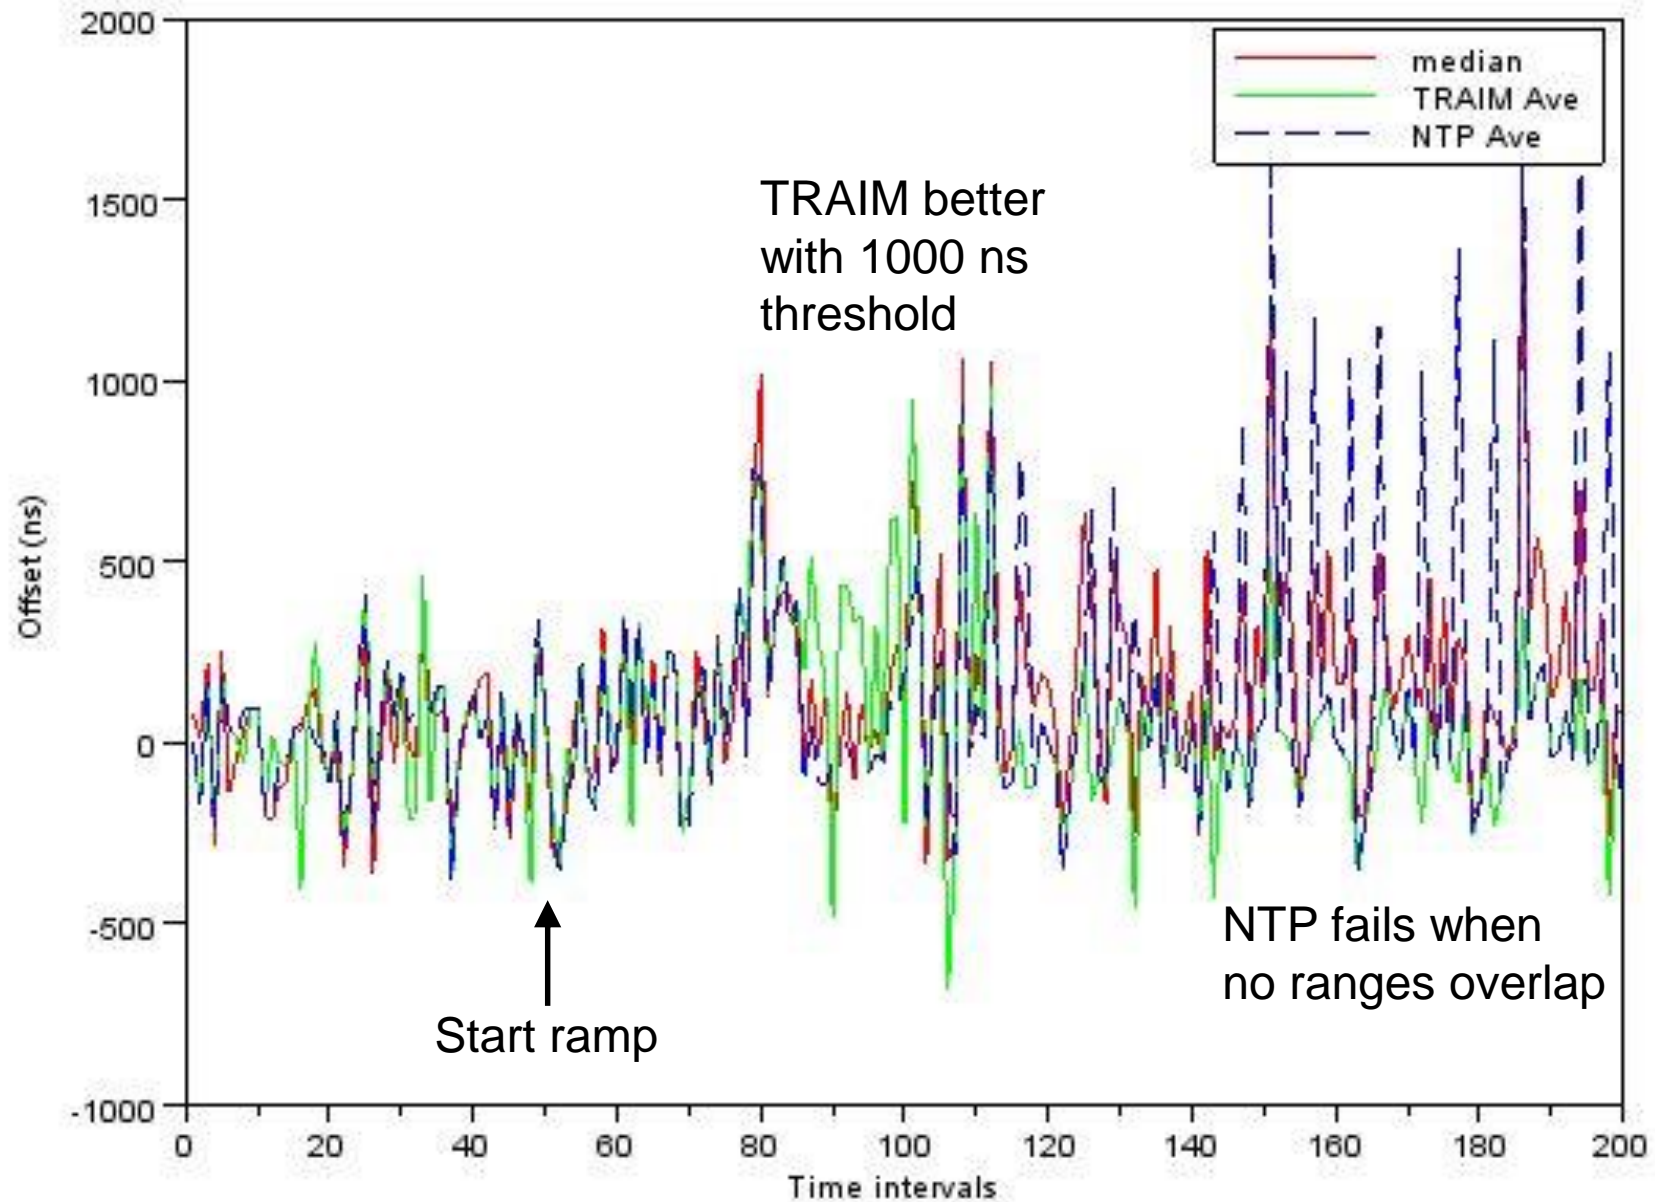

- TRAIM like
- NTP false ticker identification
- Simple median

## 3 Time Sources

- Normal random time transfer errors
  - Dequeued delays and offsets from unicast networks
  - Boundary clock networks
- False ticker
  - Ramp error

20000 time intervals, ramp starts at 5000

TRAIM threshold	NTP offset ranges	False Positives	Correct Rejections
500 ns		838	11942
1000 ns		19	9971
1500 ns		0	7538
	1 $\sigma$	1015	10046
	2 $\sigma$	32	10470
	3 $\sigma$	0	8757

PTP vulnerable to a faulty best master reporting healthy

Multiple simultaneous masters

- Combine time from multiple domains
- Proposed in IEEE 1588 Working Group

Outlier rejection filters

- Median filters
- TRAIM like filters
- NTP like filters

Outlier filters need to be tuned for network

- Trade off between outlier identification aggressiveness and false positives
- Tuning needs to adapt to variable network characteristics

Thank you for your attention
